# Text similarity 

Prof Dr Marko Robnik-Šikonja
Edition 2022

## Contents

- string similarity
- word and document similarity

## Text similarity

- morphological (respect-respectful, podoba-podobnost)
- spelling (theater-theatre, poskus - poizkus)
- sinonymy (talkative-chatty, zgovoren - gostobeseden)
- homophony (raise-raze-rays, vrat 1. skl in 2. sk vrata)
- semantic (cat-tabby, mačka-siamka)
- sentence (paraphrases)
- document (two news of the same event)
- cross-lingual (Japan-Nipon, or translated document)

## How similar are two strings?

- Spell correction
- The user typed "graffe" • Align two sequences of nucleotides
- Computational Biology
- graf
- graft
- grail
- giraffe

AgGCTATCACCTGACCTCCAGGCCGATGCCC
TAGCTATCACGACCGCGGTCGATTTGCCCGAC

- Resulting alignment:
- AGGCTATCACCTGACCTCCAGGCCGA--TGCCC---

TAG-CTATCAC--GACCGC--GGTCGATTTGCCCGAC

- Also for Machine Translation, Information Extraction, Speech Recognition

## Edit Distance

- The minimum edit distance between two strings is the minimum number of editing operations
- Insertion
- Deletion
- Substitution
- needed to transform one into the other
- Example: intention and execution

## Minimum Edit Distance

- Two strings and their alignment:

## I NTE*NTION <br>  * E X E C U T O N

## Minimum Edit Distance

```
INTE * NTION
```

```
* E X E C U T I ON
d s s i s
```

- If each operation has cost of 1
- Distance between these is 5
- If substitutions cost 2 (Levenhstein)
- Distance between them is 8

## Alignment in Computational Biology

- Given a sequence of bases

## AGGCTATCACCTGACCTCCAGGCCGATGCCC TAGCTATCACGACCGCGGTCGATTTGCCCGAC

- An alignment:
-AGGCTATCACCTGACCTCCAGGCCGA--TGCCC---
TAG-CTATCAC--GACC $G$ C--GGTCGATTTGCCCGAC
- Given two sequences, align each letter to a letter or gap

## Other uses of Edit Distance in NLP

- Evaluating Machine Translation and speech recognition

| $R$ | Spokesman confirms | senior government | adviser was shot |  |
| :---: | :---: | :---: | :---: | :---: |
| H Spokesman said | the senior |  | adviser was shot dead |  |
|  | S | $I$ | $D$ |  |

- Named Entity Extraction and Entity Coreference
- IBM Inc. announced today
- IBM profits
- Stanford President John Hennessy announced yesterday
- for Stanford University President John Hennessy

## How to find the Min Edit Distance?

- Searching for a path (sequence of edits) from the start string to the final string:
- Initial state: the word we're transforming
- Operators: insert, delete, substitute
- Goal state: the word we're trying to get to
- Path cost: what we want to minimize: the number of edits

## Minimum Edit as Search

- But the space of all edit sequences is huge!
- We can't afford to navigate naïvely
- Lots of distinct paths wind up at the same state.
- We don't have to keep track of all of them
- Just the shortest path to each of those revisited states.

## Defining Min Edit Distance

- For two strings
- X of length $N$
- $Y$ of length $M$
- We define $D(i, j)$
- the edit distance between $\mathrm{X}[1 . . i]$ and $\mathrm{Y}[1 . . j]$
- i.e. the first $i$ characters of $X$ and the first $j$ characters of $Y$
- The edit distance between $X$ and $Y$ is thus $D(N, M)$

## Dynamic Programming for Minimum Edit Distance

- Dynamic programming: A tabular computation of $D(n, m)$
- Solving problems by combining solutions to subproblems.
- Bottom-up
- We compute $D(i, j)$ for small $i, j$
- And compute larger $D(i, j)$ based on previously computed smaller values
- i.e. compute $\mathrm{D}(\mathrm{i}, \mathrm{j})$ for all $\mathrm{i}(0<i<N)$ and $j(0<j<M)$

## Defining Min Edit Distance (Levenshtein)

- Initialization
$D(i, 0)=i$
$D(0, j)=j$
- Recurrence Relation:

$$
\begin{aligned}
& \text { For each i }=1 \ldots M \\
& \text { For each } j=1 \ldots \text {...N } \\
& \qquad D(i, j)=\min \left\{\begin{array}{l}
D(i-1, j)+1 \\
D(i, j-1)+1 \\
D(i-1, j-1)+\left\{\begin{array}{l}
2 ; \\
0 ; \\
\text { if } X(i) \neq Y(j)
\end{array}\right.
\end{array} \begin{array}{l}
\text { if } X(i)=Y(j)
\end{array}\right.
\end{aligned}
$$

- Termination:

D(N,M) is distance

## The Edit Distance Table

| N | 9 |  |  |  |  |  |  |  |  |  |

## Computing alignments

- Edit distance isn't sufficient
- We often need to align each character of the two strings to each other
- We do this by keeping a "backtrace"
- Every time we enter a cell, remember where we came from
- When we reach the end,
- Trace back the path from the upper right corner to read off the alignment

$$
D(i, j)=\min \left\{\begin{array}{l}
D(i-1, j)+1 \\
D(i, j-1)+1 \\
D(i-1, j-1)+
\end{array}\right.
$$

Table for ED

## Adding Backtrace to Minimum Edit Distance

- Base conditions:

$$
D(i, 0)=i \quad D(0, j)=j
$$

- Recurrence Relation:

$$
\begin{aligned}
& \text { For each i = 1...M } \\
& \text { For each } j=1 \ldots . . \mathrm{N} \\
& \begin{array}{l}
D(i, j)=\min \begin{cases}D(i-1, j)+1 \\
D(i, j-1)+1 \\
D(i-1, j-1)+ & \text { deletion } \\
2 ; & \text { if } X(i) \neq Y(j) \text { substion } \\
0 ; & \text { if } X(i)=Y(j)\end{cases} \\
\operatorname{ptr}(i, j)= \begin{cases}\text { LEFT } & \text { insertion } \\
\text { DOWN } & \text { deletion } \\
\text { DIAG } & \text { substitution }\end{cases}
\end{array}
\end{aligned}
$$

## The Distance Matrix

Every non-decreasing path
from $(0,0)$ to $(M, N)$
corresponds to
an alignment
of the two sequences

An optimal alignment is composed of optimal subalignments

## Result of Backtrace

- Two strings and their alignment:

$$
\begin{aligned}
& \text { INTE*NTION } \\
& \text { | | | | | | | | | | } \\
& \text { * EXECUTION }
\end{aligned}
$$

## Performance

- Time: O(NM)
- Space: O(NM)
- Backtrace: O(N+M)

## Weighted Edit Distance

- Why would we add weights to the computation?
- Spell Correction: some letters are more likely to be mistyped than others
- Biology: certain kinds of deletions or insertions are more likely than others

# пипшшния 

## Confusion matrix for spelling errors

$\operatorname{sub}[X, Y]=$ Substitution of $X$ (incorrect) for $Y$ (correct)

| X |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |

## Weighted Min Edit Distance

- Initialization:
$D(0,0)=0$
$D(i, 0)=D(i-1,0)+\operatorname{del}[x(i)] ; \quad 1<i \leq N$
$D(0, j)=D(0, j-1)+i n s[y(j)] ; \quad 1<j \leq M$
- Recurrence Relation:

$$
D(i, j)=\min \begin{cases}D(i-1, j) & +\operatorname{del}[x(i)] \\ D(i, j-1) & +i n s[y(j)] \\ D(i-1, j-1) & +\operatorname{sub}[x(i), y(j)]\end{cases}
$$

- Termination:

D (N,M) is distance

## Where did the name, dynamic programming, come from?

...The 1950s were not good years for mathematical research. [the] Secretary of Defense ...had a pathological fear and hatred of the word, research...

I decided therefore to use the word, "programming".

I wanted to get across the idea that this was dynamic, this was multistage... I thought, let's ... take a word that has an absolutely precise meaning, namely dynamic... it's impossible to use the word, dynamic, in a pejorative sense. Try thinking of some combination that will possibly give it a pejorative meaning. It's impossible.

Thus, I thought dynamic programming was a good name. It was something not even a Congressman could object to."

Richard Bellman, "Eye of the Hurricane: an autobiography" 1984.

## Word and document similarity

## Motivation: document retrieval

- Historical: keywords
- Now: whole text search
- How to: organize a database, index, design search algorithms
- Input: a query (of questionable quality, ambiguity, answer quality)

## Document indexing

- Collect all words from all documents, use lemmatization
- Full text search index is called inverted file
- For each word keep
- Number of appearing documents
- Overall number of appearances
- For each document
- Number of appearances
- Location

Token DocCnt FreqCnt Head

## Construction of inverted file

## Query processing: AND

- Consider processing the query:

## Brutus AND Caesar

- Locate Brutus in the Dictionary;
- Retrieve its postings.
- Locate Caesar in the Dictionary;
- Retrieve its postings.
- "Merge" the two postings (intersect the document sets):

## The merge

- Walk through the two postings simultaneously, in time linear in the total number of postings entries

$$
\left\langle\begin{array}{|c|c|c|c||}
\hline 2 \rightarrow 4-16-32 \rightarrow 64-128 & \text { Brutus } \\
\hline 1-2 \rightarrow 3 \rightarrow 5 \rightarrow 8 \rightarrow 13-21-34 & \text { Caesar } \\
\hline
\end{array}\right.
$$

If the list lengths are $x$ and $y$, the merge takes $O(x+y)$

## operations.

Crucial: postings sorted by docID.

## Full text search engine

- Most popular: Apache Lucene/Solr
- full-text search, hit highlighting, real-time indexing, dynamic clustering, database integration, NoSQL features, rich document (e.g., Word, PDF) handling.
- distributed search and index replication, scalability and fault tolerance.

## Search with logical operators

- AND, OR, NOT
- jaguar AND car jaguar AND NOT animal
- Some system support neighborhood search (e.g., NEAR) and stemming (!) paris! NEAR(3) fr! president NEAR(10) bush
- libraries, concordancers

## Logical operator search is limited

- A large number of results
- Large specialized incomprehensible queries
- Problems with synonyms
- Sorting of results?
- No partial matching
- No weighting of query terms

## Ranking based search

- Web search
- Less frequent terms are more informative
- Sentence input - stop words, lemmatization
- Vector based representation of documents and queries (bag-of-words or dense embeddings)
