

# Inference and explanation of prediction models

Prof Dr Marko Robnik-Šikonja

Intelligent Systems, November 2020

# Overview of topics

- Visualization and knowledge discovery.
- General methodology for explaining predictive models.
- Model level and instance level explanations, methods EXPLAIN and IME.

# Visualization

- 1<sup>st</sup> rule of data mining: know your data.
- Therefore: visualizations, getting background data.
- Visualize: distributions of individual variables, their relations, etc.
- For high dimensional data sets one can use scaling.
- Clustering is useful in supervised tasks to get insight into the relation between predicted values  $Y$  and basic groups in the data. If unrelated, feature set might need amendments.

# Visualizations

- Human visual perception has certain limitations:
  - we see what we want to see
  - we see what we see often
  - it is more difficult to notice unexpected patterns
- practice in detection of unknown
- use visualizations which expose “the unknown”

Are the horizontal lines parallel or do they slope?

How many legs does this elephant have?

# Human pattern recognition

- We see inexistent patterns because we WANT to see them (we feel lost without them).

“The researchers found that when people were primed to feel out of control, they were more likely to see patterns where none exist.” (**See a Pattern on Wall Street?**, [John Tierney](#), *Science*)

# Facts about simple visualizations

- Pie charts are a bad choice: hard to read, similar colors, slope, legend is too far away
- Bar chart is much better

## Sector Allocation of Holding

The best pie chart

# Pie charts jokes

- notoriously bad

# Facts about simple visualizations

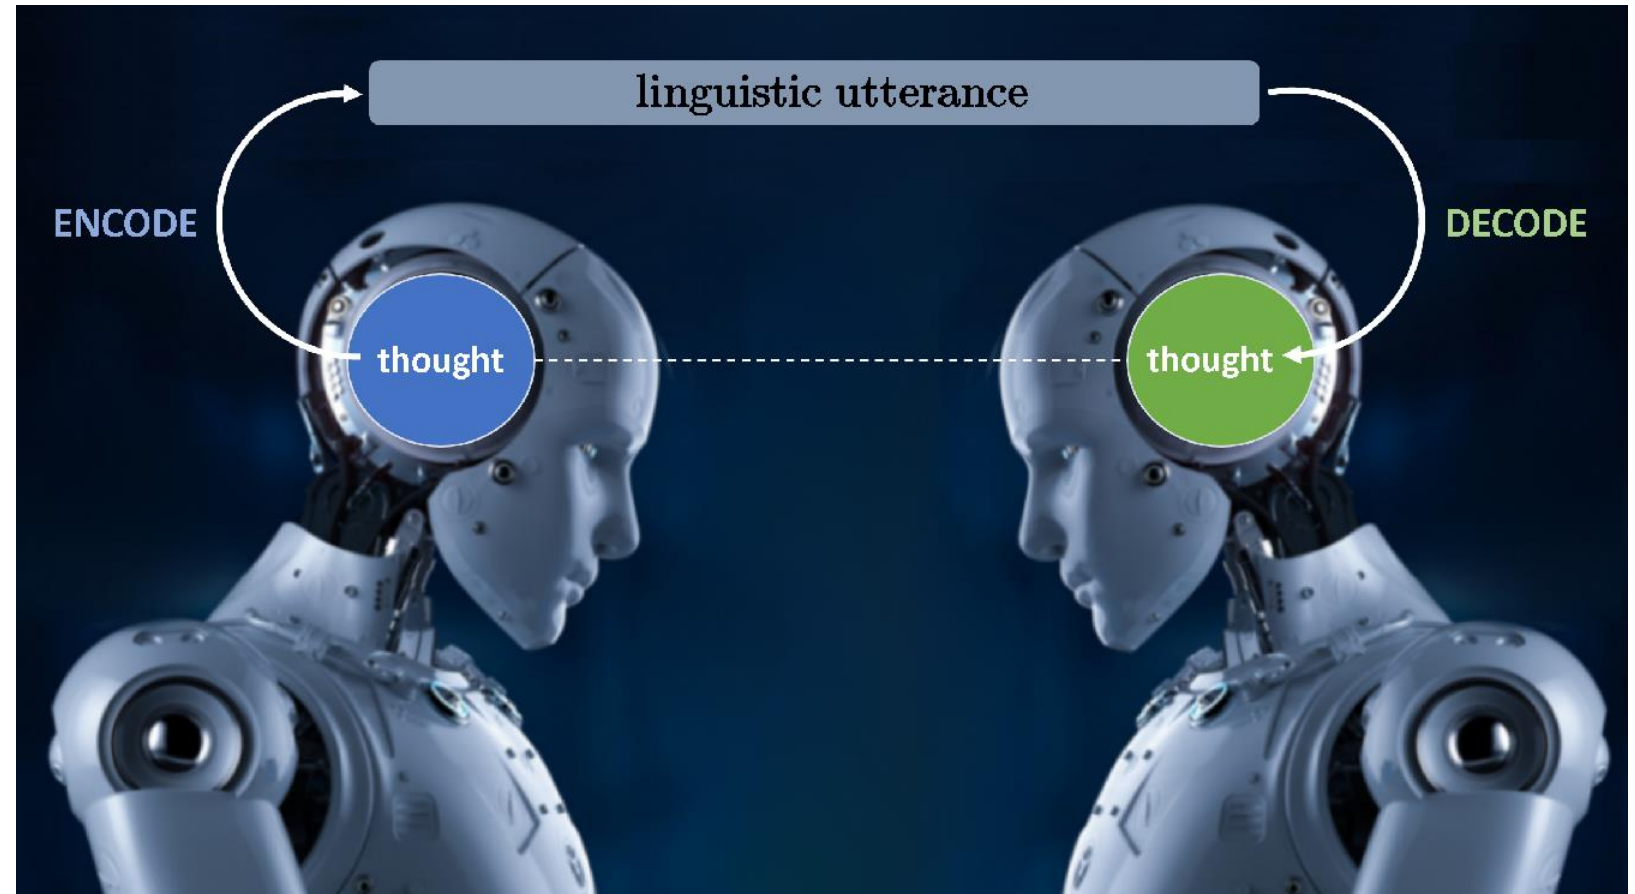

- bar charts, box plots can be OK
- 3D graphs are almost never OK for 2D info: spider plot, bowl of noodles
- take care to be clear and do not manipulate

# Understanding

Walid Saba, "Machine Learning Won't Solve Natural Language Understanding", The Gradient, 2021.

*Xanadu, who is a living young human adult, and who was in graduate school, quit graduate school to join a software company that had a need for a new employee.*

≈

*Xanadu quit graduate school to join a software company.*

# Understanding ML models is difficult

# Predictive modeling scenario

We want to learn from past examples, with known outcomes.

To predict the outcome for a new patient.

# Explanation of predictions

- a number of successful prediction algorithms exist (SVM, boosting, random forests, neural networks), but to a user they are

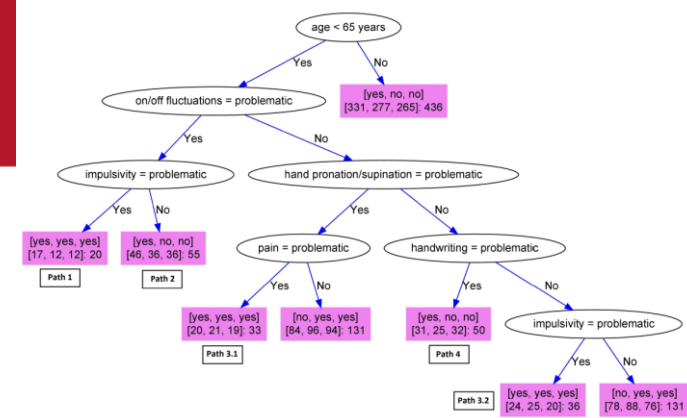

- many fields where users are very much concerned with the transparency of the models: medicine, law, consultancy, public services, etc.
- Goal: a general method applicable to an arbitrary predictor.

# Model comprehensibility

- decision support: model comprehensibility is important to gain users' trust
- knowledge acquisition
- some models are inherently interpretable and comprehensible
- decision and regression trees, classification and regression rules, linear and logistic regression
- really?

# Domain level explanation

- trying to explain the “true causes and effects”
  - physical processes
  - stock exchange events
- usually unreachable except for artificial problems with known relations and generator function
- some aspects are covered with attribute evaluation, detection of redundancies, ...
- targeted indirectly through the models

# Model-based explanations

All models are wrong,  
but some are useful.

George Box, British statistician (1919 – 2013)

- make transparent the prediction process of a particular model
- the correctness of the explanation is independent of the correctness of the prediction but
- better models (with higher prediction accuracy) enable in principle better explanation at the domain level
- we are mostly interested only in the explanation at the model level and leave to the developer of the model the responsibility for its prediction accuracy

# Two flavours of explanation techniques

- model specific
  - especially used for deep neural networks

Melis, D.A. and Jaakkola, T., 2018. Towards robust interpretability with self-explaining neural networks. In *Advances in Neural Information Processing Systems* (pp. 7786-7795).

- model agnostic
  - can be used for any predictor,
  - based on perturbation of the inputs

# Idea of perturbation-based explanations

- importance of a feature or a group of features in a specific model can be estimated by simulating lack of knowledge about the values of the feature(s)

# Instance-level explanation

- explain predictions for each instance separately
  - this is what practitioners applying models are interested in
  - presentation format: impact of each feature on the prediction value
- model-based

Data set: titanic; model: naive Bayes  
 $p(\text{survived}=\text{yes}|\mathbf{x}) = 0.50$ ; true survived=yes

# Model-level explanation

- the overall picture of a problem the model conveys
  - this is what knowledge extractors are interested in
  - presentation format: overall importance of each feature, but also rules, trees
- model-based

# The method EXPLAIN

- “hide” one attribute at a time
- estimate contribution of attribute from

$$p(y_k | x) - p_{S \setminus \{i\}}(y_k | x)$$

Robnik-Sikonja, M., & Kononenko, I. (2008). Explaining classifications for individual instances. *IEEE Transactions on Knowledge and Data Engineering*, 20(5), 589-600.

# Explaining EXPLAIN

- assume an instance  $(\mathbf{x}, y)$ , components of  $\mathbf{x}$  are values of attributes  $A_i$
- for a new instance  $\mathbf{x}$ , we want to know what role each attribute's value play in the prediction model  $f$ , i.e. to what extent it contributed to the classification  $f(\mathbf{x})$
- for that purpose
  - we compute  $f(\mathbf{x} \setminus A_i)$ , the model's prediction for  $\mathbf{x}$  without the knowledge of the event  $A_i = a_k$  (marginal prediction)
  - we comparing  $f(\mathbf{x})$  and  $f(\mathbf{x} \setminus A_i)$  to assess importance of  $A_i = a_k$
  - the larger the the difference the more important the role of  $A_i = a_k$  in the model
- $f(\mathbf{x})$  and  $f(\mathbf{x} \setminus A_i)$  are source of explanations

# Evaluation of prediction differences

- how to evaluate  $f(\mathbf{x}) - f(\mathbf{x} \setminus A_i)$
- in classification, we take  $f(\mathbf{x})$  in the form of probability

## 1. difference of probabilities

$$\text{probDiff}_i(y|\mathbf{x}) = p(y|\mathbf{x}) - p(y|\mathbf{x} \setminus A_i)$$

## 2. information gain (Shannon, 1948)

$$\text{infGain}_i(y|\mathbf{x}) = \log_2 p(y|\mathbf{x}) - \log_2 p(y|\mathbf{x} \setminus A_i)$$

## 3. weight of evidence also log odds ratio (Good, 1950)

$$\text{odds}(z) = p(z) / (1 - p(z))$$

$$\text{WE}_i(y|\mathbf{x}) = \log_2 \text{odds}(y|\mathbf{x}) - \log_2 \text{odds}(y|\mathbf{x} \setminus A_i)$$

# Implementation

- $p(y|\mathbf{x})$ : classify  $\mathbf{x}$  with the model
- $p(y|\mathbf{x}\setminus A_i)$  – simulate lack of knowledge of  $A_i$  in the model
  - replace with special NA value: good for some, mostly bad, left to the mercy of model's internal mechanism
  - average prediction across perturbations of  $A_i$   
$$p(y|\mathbf{x}\setminus A_i) = \sum_a p(A_i=a_s) p(y|\mathbf{x} \leftarrow A_i = a_s)$$
  - use discretization for numeric attributes
  - use Laplace correction for probability estimation
  - we could build a separate model for each  $p(y|\mathbf{x}\setminus A_i)$

# Weaknes of EXPLAIN

- “hide” one attribute at a time
- estimate contribution of attribute from

$$p(y_k | x) - p_{S \setminus \{i\}}(y_k | x)$$

- weakness: if there are redundant ways to express concept, credit is not assigned
- example:

$$C = A_1 \vee A_2 A_3$$

explanation for instance ( $A_1=A_2=A_3=1$ )

# The method IME

- (Interactions-based Method for Explanation)
- “hide” any subset of attributes at a time ( $2^a$  subsets!)
- the source of explanations is the difference in prediction using a subset of features  $Q$  and an empty set of features  $\{\}$

$$\Delta_Q = h(x_Q) - h(x_{\{\}})$$

- the feature gets some credit for standalone contributions and for contributions in interactions

# IME: sum over all subsets

- the contributions are

$$\pi_i = \sum_{Q \subseteq \{1, 2, \dots, a\} - \{i\}} \frac{1}{a \binom{a-1}{a-|Q|-1}} (\Delta_{Q \cup \{i\}} - \Delta_Q)$$

# Game theory analogy

- coalitional game of  $a$  players (attributes)
- players form coalitions (i.e. interactions)
- how to distribute the payout to the members of a coalition: (how to assign the credit for prediction)
- The Shapley value is the unique payoff vector that is
  - efficient (exactly splits payoff value),
  - symmetric (equal payments to equivalent players)
  - additive (overall credit is a sum of participating in coalitions), and
  - assigns zero payoffs to dummy players (no contribution to any coalition).

# Shapley value

$$Sh_i(v) = \sum_{S \subseteq N \setminus \{i\}, s=|S|} \frac{(n-s-1)!s!}{n!} (v(S \cup \{i\}) - v(S)), \quad i = 1, \dots, n.$$

$$\pi_i = \sum_{Q \subseteq \{1, 2, \dots, a\} - \{i\}} \frac{1}{a \binom{a-1}{a-|Q|-1}} (\Delta_{Q \cup \{i\}} - \Delta_Q)$$

- Shapley value can be efficiently approximated

- Shapley value can be expressed in an alternative formulation
- $\pi(a)$  is the set of all ordered permutations of  $a$
- $\text{Pre}^i(\mathcal{O})$  is the set of players which are predecessors of player  $i$  in the order  $\mathcal{O} \in \pi(a)$

$$\begin{aligned}\varphi_i(k, x) &= \frac{1}{a!} \sum_{\mathcal{O} \in \pi(a)} (\Delta(\text{Pre}^i(\mathcal{O}) \cup \{i\})(k, x) - \Delta(\text{Pre}^i(\mathcal{O}))(k, x)) = \\ &= \frac{1}{a!} \sum_{\mathcal{O} \in \pi(a)} (p_{\text{Pre}^i(\mathcal{O}) \cup \{i\}}(y_k | x) - p_{\text{Pre}^i(\mathcal{O})}(y_k | x)),\end{aligned}$$

- smart sampling over subsets of attributes
- computationally feasible approach

# IME algorithm

---

**Algorithm 1** Approximating the contribution of the  $i$ -th feature's value,  $\varphi_i$ , for instance  $x \in \mathcal{A}$ .

---

determine  $m$ , the desired number of samples

$\varphi_i \leftarrow 0$

**for**  $j = 1$  to  $m$  **do**

    choose a random permutation of features  $O \in \pi(N)$

    choose a random instance  $y \in \mathcal{A}$

$v_1 \leftarrow f(\tau(x, y, Pre^i(O) \cup \{i\}))$

$v_2 \leftarrow f(\tau(x, y, Pre^i(O)))$

$\varphi_i \leftarrow \varphi_i + (v_1 - v_2)$

**end for**

$\varphi_i \leftarrow \frac{\varphi_i}{m}$

- by measuring the variance of contributions, we can determine the necessary number of samples for each attribute

# Visualization of explanations

- instance-level explanation on Titanic data set

# Visualization of explanations

- model-level explanation on Titanic data set

# LIME explanation method

- Local Interpretable Model-agnostic Explanations)
- perturbations in the locality of an explained instance

# LIME explanation method

- optimize a trade-off between local fidelity of explanation and its interpretability

$$e(x) = \arg \min_{g \in G} L(f, g, \pi) + \Omega(g)$$

- L is a local fidelity function, f is a model to be explained, g is an interpretable local model g (i.e. linear model),  $\pi(x, z)$  is proximity measure between the explained instance x and perturbed points z in its neighborhood,  $\Omega$  is a model complexity measure

# LIME details

- LIME samples around the explanation instance  $x$  to draw samples  $z$  weighted by the distance  $\pi(x, z)$
- samples  $z$  are used to training an interpretable model  $g$  (linear model)
- the squared loss measures local infidelity
- number of non-zero weights is complexity
- samples are weighted according to the Gaussian distribution of the distance between  $x$  and  $z$

# LIME strengths and weaknesses

- faster than IME
- works for many features, including text and images
- no guarantees that the explanations are faithful and stable
- neighborhood based: a curse of dimensionality
- may not detect interactions due to (too) simple interpretable local model (linear model)

# SHAP

- SHapley Additive exPlanation
- unification of several explanation methods, including IME and LIME
- KernelSHAP: based on Shapley values which are estimated using a LIME style linear regression
- faster than IME but
- still uses linear model with all its strengths and weaknesses

# Use case: breast cancer recurrence

Data set: onko; model: PRBF  
 $p(\text{recurrence}=1|x) = 0.81$ ; true recurrence=2

## Cancer recurrence within 10 years

*menop* binary feature indicating menopausal status

*stage* tumor stage 1: less than 20mm, 2: between 20mm and 50mm, 3: over 50mm

*grade* tumor grade 1: good, 2: medium, 3: poor, 4: not applicable, 9: not determined

*histType* histological type of the tumor 1: ductal, 2: lobular, 3: other

*PgR* level of progesterone receptors in tumor (in fmol per mg of protein) 0: less than 10, 1: more than 10, 9: unknown

*invasive* invasiveness of the tumor 0: no, 1: invades the skin, 2: the mamilla, 3: skin and mamilla, 4: wall or muscle

*nLymph* number of involved lymph nodes 0: 0, 1: between 1 and 3, 2: between 4 and 9, 3: 10 or more

*famHist* medical history 0: no cancer, 1: 1st generation breast, ovarian or prostate cancer, 2: 2nd generation breast, ovarian or prostate cancer, 3: unknown gynecological cancer, 4: colon or pancreas cancer, 5: other or unknown cancers, 9: not determined

*LVI* binary feature indicating lymphatic or vascular invasion

*ER* level of estrogen receptors in tumor (in fmol per mg of protein) 1: less than 5, 2: 5 to 10, 3: 10 to 30, 4: more than 30, 9: not determined

*maxNode* diameter of the largest removed lymph node 1: less than 15mm, 2: between 15 and 20mm, 3: more than 20mm

*posRatio* ratio between involved and total lymph nodes removed 1: 0, 2: less than 10%, 3: between 10% and 30%, 4: over 30%

*age* patient age group 1: under 40, 2: 40-50, 3: 50-60, 4: 60-70, 5: over 70 years

# Use case: breast cancer recurrence

Data set: onko; model: PRBF  
 $p(\text{recurrence}=1|x) = 0.81$ ; true recurrence=2

Data set: onko; model: PRBF  
 $p(\text{recurrence}=1|x) = 0.06$ ; true recurrence=2

# Use case: breast cancer recurrence

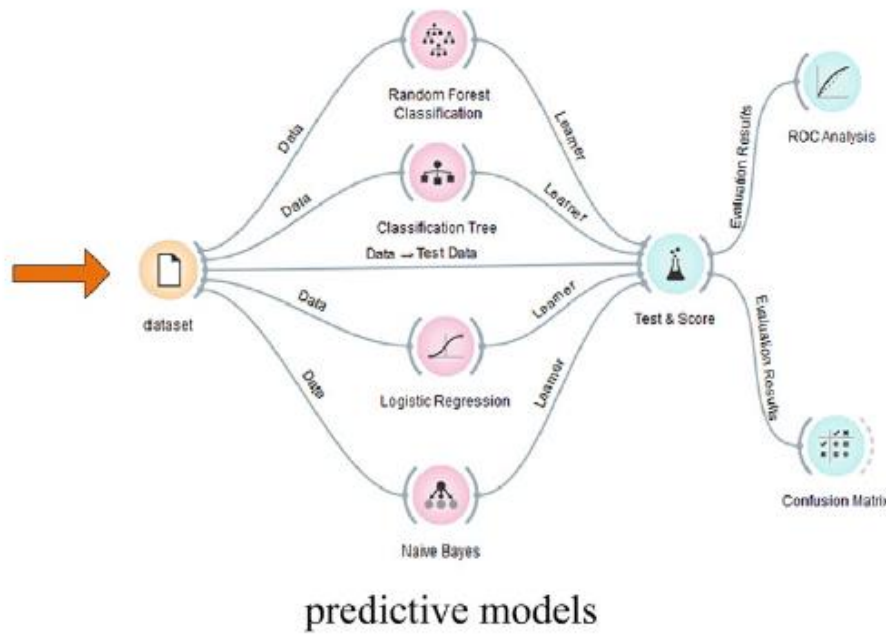

# Use case: B2B sales forecasting

- Goals: improve understanding of factors influencing the outcome and improve the sales performance

B2B sales experts

predictive models

New insights

explanation

decision

# B2B sales attributes

Attribute	Description	Values
Authority	Authority level at a client side	Low, mid, high
Product	Offered product	e.g. A, B, C, etc.
Seller	Seller's name	Seller's name
Competitors	Do we have competitors?	No, yes, unknown
Company size	Size of a company	Big, mid, small
Purchasing department	Is the purchasing department involved?	No, yes, unknown
Partnership	Selling in partnership?	No, yes
Budget allocated	Did the client reserve the budget?	No, yes, unknown
Formal tender	Is a tendering procedure required?	No, yes
RFI	Did we get request for information?	No, yes
RFP	Did we get request for proposal?	No, yes
Growth	Growth of a client?	Growth, stable, etc.
Positive statements	Positive attitude expressed?	No, yes, neutral
Source	Source of the opportunity	e.g. referral, web, etc.
Client	Type of a client	New, current, past
Cross sale	A different product to existing client?	No, yes
Scope clarity	Implementation scope defined?	Clear, few questions, etc.
Strategic deal	Does this deal have a strategic value?	Very important, etc.
Up sale	Increasing sales of existing products?	No, yes
Deal type	Type of a sale	Consulting, project, etc.
Needs defined	Is client clear in expressing the needs?	Info gathering, etc.
Attention to client	Attention to a client	First deal, normal, etc.
Status	An outcome of sales opportunity	Lost, won

# B2B sales: drill in

# B2B sales: EXPLAIN and IME

method EXPLAIN, type WE

method IME

# B2B sales: learning from errors

**Explanation case, Status = Won**  
instance: 116, model: rf

method IME  
 $p(\text{Status}=\text{Won}) = 0.71$ ; true Status=Lost

**Explanation case, Status = Won**  
instance: 204, model: rf

method IME  
 $p(\text{Status}=\text{Won}) = 0.38$ ; true Status=Won

# B2B: what if

What-if case, Status = Won  
instance: new, model: rf

method IME  
p(Status=Won) = 0.29; true Status=Open

# B2B: change of distribution

Acquisition of new clients, Status = Won  
model: rf

# Lessons learned

- an effort needed to overcome the users' resistance
- human-in-the-loop is necessary to train, discuss, clean data, introduce explanations
- with an increased use, users gain trust in the methodology
- human mental models tend to be biased
- joint interactive approach beats both humans and ML models
- problem with slippages

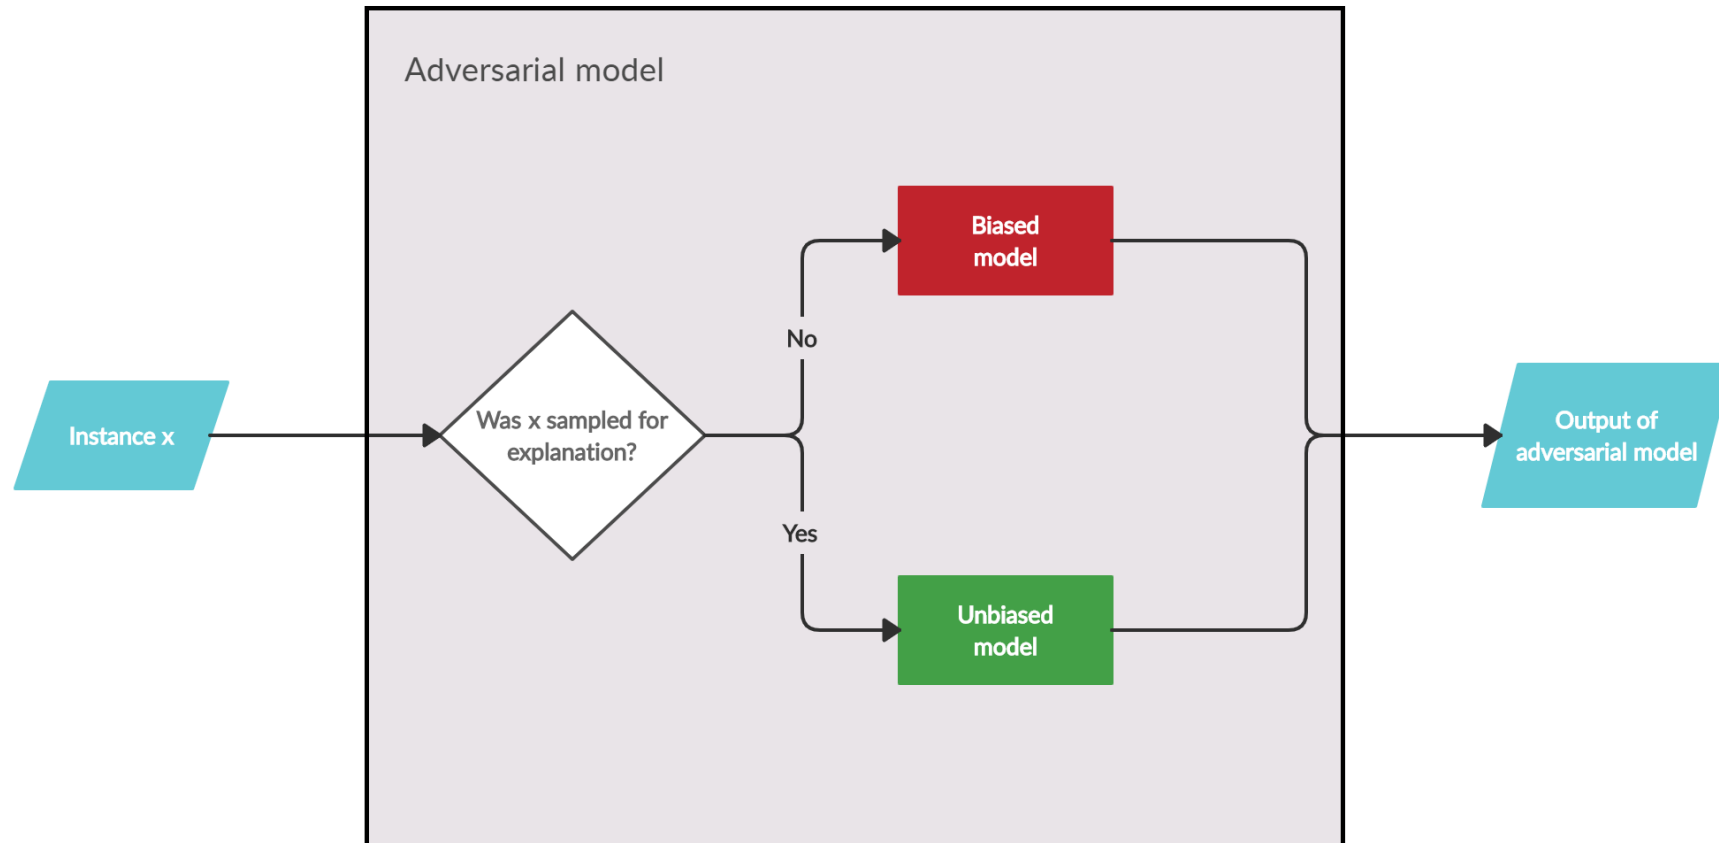

# Attacks on explanations

- Poor sampling in explanation approaches makes them vulnerable
- Example: PCA based visualization of a part of the COMPAS dataset; the red dots were generated by LIME

# Dieselpgate attacks on explanations

- Defence: better sampling

# More on explanations

- symbolic models
  - straightforward comprehensible explanation for small models (decision trees, lists, rules)
- numeric models (mostly neural networks)
  - generation of symbolic models from generated additional instances
  - resulting models are large and incomprehensible
- explanations in the form of nomograms for specific algorithm/model:
  - logistic regression, Naive Bayesian classifier, restricted decomposable kernels for SVM
- visualization of SVM with a separating hyperplane in a restricted subspace
- explanation of neural networks based on propagation of gradients
- sensitivity analysis

# Opportunities

- better and more focused sampling
- better local explanation models
- interactions: detect and describe
- sequences: the order of attributes is important!
- images: decision areas, super-pixels
- better visualizations: human cognitive limitations

# Conclusions

- many successful approaches but
- lots of opportunities for improvements
- legal and practical need for explanations of ML models
